Abstract

A new family of functional quinolizidine alkaloids containing alkoxy groups and phosphine or phosphine chalcogenide fragments has been prepared from the vinyl ether of enantiomerically pure lupinine, secondary phosphines and phosphine sulfide. The reaction proceeds readily under radical initiation to give anti-Markovnikov adducts, dialkyl[2-(octahydro-2H-quinolin-1-ylmethoxy)ethyl]phosphines and -phosphine sulfide, in high yields (89-96%). The phosphine moieties of the alkaloids synthesized have been oxidized with air, elemental sulfur or selenium to afford the corresponding phosphine chalcogenides.

Keywords: Vinyl ether of lupinine, secondary phosphines and phosphine chalcogenides, radical addition, functional quinolizidine alkaloids

Introduction

Quinolizidine alkaloids are widely distributed in plants.¹ They possess a diverse range of biological activities, *e.g.* cardiotonic and myotonic,² anticancer,³ anti-HBV,⁴ antimicrobial and antibacterial.⁵ They also affect the nervous system state.⁶ Much attention from researchers is now focused on the study of the biological activity of quinolizidine alkaloid derivatives to design drugs of new generation.⁷ For example, lupinine derivatives are prospective ligands for sigma receptors in the central nervous system, which are implicated in the pathogenesis of psychiatric and motor disorders.⁸ Recent data indicate the octahydroquinolizidine chemotype is the structural motif of derivatives with calcium channel antagonist activity⁹ as well as inhibitors of histone

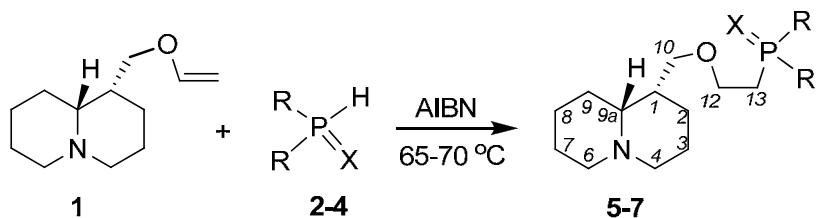

deacetylase.¹⁰ Therefore, the search for convenient methods for the preparation of novel functional quinolizidine alkaloids remains an urgent synthetic challenge.

In this paper we describe an atom-economic synthesis of previously unknown lupinine derivatives from the vinyl ether of lupinine **1** and now available secondary phosphines¹¹ or phosphine sulfides¹² readily prepared by the direct reaction of red phosphorus with alkyl halides^{11a} or styrene.^{11b} The choice of vinyl ether **1** is due to its recently described synthesis by direct vinylation of lupinine with acetylene.¹³ To date, the free radical additions of H-phosphines and H-phosphine chalcogenides to vinyl chalcogenides is just scarcely studied. Only few publications dealing with the radical addition of secondary phosphines and phosphine chalcogenides to vinyl ethers are known.¹⁴

Results and Discussion

Secondary phosphines **2**, **3** and phosphine sulfide **4** add to vinyl ether **1** regiospecifically in the presence of azaisobutyronitrile (AIBN) at 65-70 °C to form the corresponding optically active tertiary dialkyl[2-(octahydro-2*H*-quinolizin-1-ylmethoxy)ethyl]phosphines **5**, **6** and -phosphine sulfide **7** in high yields (Table 1).

Conclusions

A straightforward atom-economic (“green”) method for the preparation of previously unknown alkaloid derivatives containing lupinine core, alkoxy groups and phosphine or phosphine chalcogenide fragments, using vinyl ether of enantiomerically pure lupinine, secondary phosphines and phosphine sulfide has been successfully developed. The functional lupinine derivatives synthesized can be widely used for the direct design of biologically active compounds as well as easily accessible enantiomerically pure chelating ligands for preparing transition metal complexes. For example, recently, tetrahedral carbonyl hydride cluster H₄Ru₄(CO)₁₁L have been synthesized using the ligand (L) di(2-phenethyl)[2-(octahydro-2H-quinolizin-1-ylmethoxy)ethyl]phosphine **6**¹⁵. The structure and dynamic behavior of the cluster in solution have been studied.

Experimental Section

General Procedures. ^1H , ^{13}C , ^{31}P and ^{77}Se NMR spectra were recorded on Bruker DPX-400 (400.13, 100.61, 161.98 and 76.26 MHz, respectively) spectrometer in CDCl_3 solutions and referenced to internal HMDS (^1H), CHCl_3 (^{13}C) and external 85% H_3PO_4 (^{31}P) and Me_2Se (^{77}Se). IR spectra were measured with a Bruker IFS 25 instrument in microlayer. Optical rotation measurements were carried out on a Polamat A polarimeter.

General procedure for the synthesis of tertiary diorganyl[2-(octahydro-2*H*-quinolizin-1-ylmethoxy)ethyl]phosphines **5**, **6** and -phosphine sulfide **7** (Table 1)

An equimolar mixture of secondary phosphine **2**, **3** or phosphine sulfide **4** and vinyl ether of lupinine **1** was heated at 65-70 °C in the presence of AIBN (0.5-1.5 wt% of the reactants' mass) in a sealed ampoule. The reaction was monitored by ^{31}P NMR spectroscopy. The crude product, a viscous undistillable liquid, was purified by column chromatography on Al_2O_3 (diethyl ether) to give the phosphine **5**, **6** or phosphine sulfide **7**. All operations were scrupulously carried out under an atmosphere of inert gas (preferably, argon).
